Mechanism and Mechanistic Explanation

Does anyone belong to clicker numbers?

Review - 1

- Experiments provide the best evidence of a causal relation, but sometimes they are not possible
  - Because it is impossible physically or morally to manipulate the independent variable
- Two strategies
  - Prospective studies
    - Divide groups according to the independent variable and investigate correlation with the dependent variable
  - Retrospective studies
    - Divide group according to the dependent variable and investigate correlation with the independent variable

Clicker Question

A possible confounding variable is

- A variable correlated with the dependent variable that might be a cause of the independent variable
- A variable correlated with the independent variable that might be a cause of the dependent variable
- A bias of experimenters to see positive results
- A reason to prefer retrospective studies as providing stronger evidence
Review - 2

- All studies of causation are beset by confounds
  Factors correlated with the independent variable that may themselves be the cause of the change in the dependent variable
- By manipulating the independent variable in an experiment, researchers reduce the risk of confounds
  Researchers can randomize or match subjects or lock (control) procedural variables to minimize confounds
- Prospective and retrospective experiments do not allow manipulation
  Greater risk of confounds. Try to reduce the risk by
  - matching subjects
  - measuring possible confounds

Clicker Question

What is the major advantage of a randomized experiment over a prospective study?

A. In an experiment one manipulates the independent variable
B. Randomizing can control for unknown subject confounds
C. Randomizing can control for unknown procedural confounds
D. There is no experimenter bias in a randomized experiment

Clicker Question

Imagine someone has traveled in time from 1885 to 2011 and is trying to figure out how a car works. They do a series of experiments from the driver's seat, without ever looking under the hood of the car, and conclude that turning the ignition key explains why the car runs. What is a major limitation of their experiments?

A. The person failed to control for subject confounds
B. The person failed to control for procedural confounds
C. The person missed the causal intermediaries that explain how the car worked
D. The person failed to consider more ultimate variables such as the refinement of gasoline
Two limitations of focusing only on causes

- Individual causal relations do not accomplish much. It often requires a coordinated system of causes to get something done.
- What relates causes to their effects?
  - Typically there are processes intervening between causes and their effects.

Much of science is concerned not with demonstrating specific causal relations, but with discovering mechanisms and explaining phenomena in terms of them. Mechanisms consist of parts (entities) and operations (activities) organized to produce a phenomenon. Mechanisms are appealed to:

- To explain causal relations
- And appeal to causal relations between their parts

The Ubiquity of Mechanisms in Science

- Mechanisms in physical sciences
  - Solar system mechanics
  - Mechanisms of chemical reactions
- Mechanisms in biological sciences
  - Mechanisms of photosynthesis
  - Mechanisms of reproduction
- Mechanisms in behavioral sciences
  - Mechanisms of memory encoding
  - Mechanisms of decision making
- Mechanisms in social sciences
  - Mechanisms of consensus formation

Mechanisms as Coordinated Causation

- Mechanisms consist of parts whose operations cause changes in other parts, enabling mechanisms to cause changes in yet other things.
- Muscles in heart contract while valves open and shut, enabling the heart to move blood through arteries and veins.
- Understanding a mechanism requires experimental procedures designed to figure out the parts, their causal operation, and how these operations are coordinated (organized) so that the mechanism can produce its effect.
Clicker Question
When a scientist is interested in the mechanism responsible for the causal effect of aspirin on pain, she is
Expressing skepticism that aspirin really affects pain
Trying to understand how aspirin affects pain
Trying to eliminate any confounds in experiments studying the affects of aspirin on pain
Trying to determine whether aspirin does affect pain

Designing Mechanisms vs. Discovering Mechanisms
• The challenge in engineering is to design new mechanisms that produce the phenomena we are interested in
   Typically, engineers begin with an objective and recruit parts already known to perform operations
   Their challenge is to discover new modes of organization that enable the parts to together do something new
• Scientists do not have access to the design manuals of the mechanisms operative in the natural world
   They must reverse engineer them—discover the parts, the operations, and the organization

Designing Mechanisms in Your Life
• Design a mechanism (set of operations) for making a beef taco
• Design a mechanism (set of operations) for getting to Kotzebue, Alaska
• Design a mechanism (set of operations) for making sure you get to class on time

Flame from lamp (A) catches on curtain (B) and fire department sends stream of water (C) through window. Dwarf (D) thinks it is raining and reaches for umbrella (E), pulling string (F) and lifting end of platform (G). Iron ball (H) falls and pulls string (I), causing hammer (J) to hit plate of glass (K). Crash of glass wakes up pup (L) and mother dog (M) rocks him to sleep in cradle (N), causing attached wooden hand (O) to move up and down along your back.

At 6:30 weight (A) automatically drops on head of dwarf (B), causing him to yell and drop cigar (C), which sets fire to paper (D). Heat from fire angers dwarf's wife (E). She sharpens potato knife (F) on grindstone (G) which turns wheel (H) causing olive spoon (I) to dip repeatedly into olives. If spoon does not lift an olive in 15 minutes, clock (J) automatically pushes glass-cutter (K) against bottle and takes out a chunk of glass big enough for you to stick your finger in and pull out an olive.
Early machines: Putting Shape to Work

- Wedge
- Ramp
- Screw

Early simple machines used human energy but extended its capacity.
- In these cases, shape and spatial layout explain the causal efficacy.

Early machines: Organizing Parts

- Lever
- Wheel
- Pulley

In these cases, shape and layout together with coordination of parts explains the effect.

Combining simple mechanisms

- Engineering: organizing components to produce effects
The Gastrophetes or belly bow, introduced around 400 BCE, designed to launch arrows further and more accurately than the traditional bow.

The Oxybeles, introduced around 375 BCE, provided ever greater power and accuracy.

Ballista, introduced around 50 BCE, used more for throwing stones than arrows.

Onager, developed around 350 CE, was a low cost way of launching projectiles such as clay balls with Greek fire inside.

Trebuchet: a counterweighted catapult designed to throw heavy projectiles such as pianos!

- Chris throwing Maggie’s piano in Northern Exposure
Nature as a machine: Rene Descartes

"I have described this earth and indeed the whole universe as if it were a machine: I have considered only the various shapes and movements of its parts" (Principia IV 188).

All action in the physical universe due to shape and motion of physical matter
- No vacuum
- No action at a distance

Magnetism: Screw-shaped particles (formed in vortices) fit into threads in iron.

Descartes: Animals as machines

Impressed by the statuary in the Royal Gardens that moved by hydraulic principles
Animal bodies are purely mechanical devices

Circulation of blood due to heating in the heart, causing the expansion of droplets of blood, which then forced their way through the arteries
Nerve transmission and brain activity purely mechanical (albeit influenced by the mind in humans)

Humans as machines

Descartes could not conceive of a mechanism that could think or use language

Accordingly, held that the human capacity for thought was not due to a mechanism
Rather, thought due to a non-material mind

Julien Offray de La Mettrie objected that Descartes did not go far enough—all human activities, including thinking explained in mechanical terms

Man the Machine in 1748
Clicker Question

In treating animal (and human) bodies as machines, Descartes was
A. Maintaining that they consisted of metallic parts that moved like the parts of a clock
B. Denying the possibility of causal explanation of the behavior of animal bodies
C. Claiming that their behavior could be explained in terms of their parts, operations, and organization
D. Claiming that it was easy to explain how animals worked

Jacques de Vaucanson (1709-1782):
“Moving Anatomy”

Mechanical duck could move in the typical, wagging way of a duck
eat and digest fish
excrete the remains in a “natural” way
Mechanism was driven by a weight
Consisted of more than a thousand moving parts, concealed inside the duck and the base on which the bird stood
Besides the duck, a flute and tambourine player

Applying mechanical ideas to living organisms

Living things seem to behave in complex ways that defy simple mechanical explanation
Vitalists maintained that the complexity and purposiveness of biological processes made mechanical explanation impossible
Mechanists developed more complex conceptions of mechanisms
Tropism

Two principles of Jacques Loeb:

(i) The movements of an organism to or from a center of a stimulus are caused by action of the stimulus on the receptors, and through these on the organs of locomotion, in consequence of which the animal turns until its body is symmetrically stimulated and an equilibrium obtained between the two sides.

(ii) These movements occur mechanically, as a result of physical and chemical changes in the receptors and effectors, with no real effort on the part of the organism.

Designing a tropistic machine
Tasks in Developing a Mechanistic Explanation

1. Describe the phenomenon
2. Identify the working parts
3. Identify the operations the parts perform
4. Discover how the parts are organized

Task 1: Describing the Phenomenon

- Before setting out to explain a phenomenon, need to characterize it as accurately as possible
  - Otherwise one risks trying to explain something that might not be possible
- An important role for purely observational research
  - Before seeking a mechanism by which the universe continues to expand, make sure it is
  - Before seeking a mechanism to explain global warming, make sure it is really occurring
- But the description of the phenomena may be revised in the process of figuring out the mechanism

Task 2: Identify the working parts

To understand a mechanism, one must decompose it—take it apart
- Literally—actually remove the parts to study them in isolation
- Figuratively—figure out what the parts are and what they do

In identifying components, focus both on their
- Structure—parts
- Function—operations

Different tools for identifying parts and operations
What are the parts of the brain?

Open up the skull, and you see a hunk of grey matter highly convoluted. What are the working parts of the brain?

Korbinian Brodmann (1909) assumed differences in neuron type, density, and layering were probably related to function. Delineated areas in the brains of humans and many other species.

What are the working parts of the brain?

Task 3: What operations do the components perform?

Often one must reason backwards from what the whole mechanism does to what operations are needed to perform that activity. Often these operations are not obvious:
- Reverse engineering
- Figuring out what task needs to be performed
- Using information about the type of operations that have been previously identified in similar systems
- Drawing upon analogies with machines made by humans.
Clicker Question
The goal in decomposing a mechanism is
A. To find out how the parts are organized to produce the phenomenon of interest
B. To render the mechanism inoperable
C. To identify the parts and operations in the mechanism
D. To show that the mechanism doesn’t do what it is claimed to do

What are the operations in fermentation?

Strategies of discovering intermediate operations

- Isolate possible intermediaries
  - Inhibit possible intermediate processes to see if that stops the reaction—lesion experiment
  - Insert possible intermediaries to see if they could produce the end product—excitation experiment
  - Record from possible intermediates as the mechanism is operating to determine what they respond to—recording experiment
Task 4: Discover How the Parts are Organized

- The third feature of mechanisms is that they are organized and that the organization matters.
- Grains of sand in a sand pile are not organized: you can recombine the grains at will and nothing happens.
- In mechanisms, the operation of one part depends on that of others, so organization is crucial.

Organization is critical to the operation of a lock.

Using diagrams to portray organization

It is very difficult to understand the organization of a complex system from a verbal description. Diagrams are able to show in two dimensions the spatial layout of a mechanism. Often, though, diagrams must also show the activity of the mechanism:

- This is often done through arrows.
- Sometimes through sequences of diagrams.
- Increasingly, by animating diagrams.
Diagramming steps in a process in separate diagrams

Show organization at successive stages in the process of cell division
Use arrows to reflect the progression of stages

Diagramming steps in a process in a common diagram

Use arrows to trace the movement of components from one location to another: here, move various RNAs from the DNA of the nucleus to the ribosomes in the cytoplasm

Beyond Sequential Organization

Negative Feedback
In many mechanisms, operations later in a sequence serve to inhibit (subsequent iterations) of operations earlier in a sequence
- Important for maintaining system in desired condition

Positive Feedback
It is also common for operations later in a sequence to promote (subsequent iterations) of operations earlier in a sequence

Integrated Systems
Such organization renders a set of operations into a cohesive, and often stably enduring systems—organisms
- The heart
- A circadian clock
Clicker Question
A general use of negative feedback is
   To raise the number of negative outcomes
   To insure maximal efficiency in the operation of a
   mechanism
   To keep the operation of a mechanism within
   boundaries
   To make sure that predators don't destroy their
   prey

Organization creates systems
If the organization is appropriate, the components
comprise a new entity
   One that operates as a unit
   Exists at a higher-level of organization than the
   components

Often it is cyclic organization, involving later reactions
influencing ones earlier in a pathway, that turn a set of
operations into a system—a recognizable entity that does
something
   Nervous system
   Circulatory system

Levels of mechanism
- The system as a whole
  engages its environment by
  performing its activity
- That system is comprised of
  components that perform
different operations
- Those components may in
  turn be comprised of
  components that perform yet
different operations
Holism versus reductionism

Tension:
Emphasizing organization focuses on the integration of the components into a whole system (holism)
Emphasizing components focuses on the decomposition of the system into separate components (reductionism)
As a result, holism (vitalism) and reductionism are often pitted against each other
Holists charge that reductionists fail to consider the consequences of organization
Reductionists charge that holists fail to provide explanations

Mechanistic explanations: both reductionist and holist
To understand a mechanism you must be both a holist and a reductionist
Look both
Upwards to higher levels of organization at which the mechanism is an organized system that performs its activity and thereby interacts with other entities
and
Downwards to lower levels of organization in which parts perform their operations in interaction with other parts

Clicker Question
A reductionist, in contrast to a holist,
Focuses on how the components of the system fit into an integrated whole
Denies any importance to discovering the parts of the mechanism
Denies that organization plays any role in the operation of a mechanism
Emphasizes the discovery of components as the key to understanding how a mechanism behaves
Clicker Question

A holist, in contrast to a reductionist,
- Places greater emphasis on the organization of the whole than on the identification of the parts
- Thinks that the parts don’t matter; all that matters is how they are organized
- Denies that the parts of a mechanism are relevant to explaining what the mechanism does
- Places primary emphasis on discovering the parts of a mechanism
